Treatments for infected TKA:

- Irrigation, debridement
- One-stage revision
- Two-stage revision
- *Rescue treatments: Arthrodesis, Amputation, Retained spacer*

RESEARCH ARTICLE

Re-Infection Outcomes Following One- And Two-Stage Surgical Revision of Infected Knee Prosthesis: A Systematic Review and Meta-Analysis

Setor K. Kunutsor*, Michael R. Whitehouse, Erik Lenguerrand, Ashley W. Blom, Andrew D. Beswick, INFORM Team¹ Review methods

Two independent investigators extracted data and discrepancies were resolved by consensus with a third investigator. Re-infection rates from 10 one-stage studies (423 participants) and 108 two-stage studies (5,129 participants) were meta-analysed using random-effect models after arcsine transformation.

Results

The rate (95% confidence intervals) of re-infection was 7.6% (3.4–13.1) in one-stage studies. The corresponding re-infection rate for two-stage revision was 8.8% (7.2–10.6). In subgroup analyses, re-infection rates remained generally similar for several study-level and clinically relevant characteristics. Postoperative clinical outcomes of knee scores and range of motion were similar for both revision strategies.

Re-Infection Outcomes Following One- And Two-Stage Surgical Revision of Infected Knee Prosthesis: A Systematic Review and Meta-Analysis

Setor K. Kunutsor*, Michael R. Whitehouse, Erik Lenguerrand, Ashley W. Blom, Andrew D. Beswick, INFORM Team $^{1\!\!1}$

Conclusions

Available evidence from aggregate published <u>data suggest the one-stage revision strategy</u> may be as effective as the two-stage revision strategy in treating infected knee prostheses in generally unselected patients. Further investigation is warranted.

Unselected patients ? Historical bias !

One-stage versus two-stage exchange arthroplasty for infected total knee arthroplasty: a systematic review

Navraj S. Nagra
1,2 \cdot Thomas W. Hamilton
2 \cdot Sameer Ganatra
2 \cdot David W. Murray
2 \cdot Hemant Pandit²

Conclusion Recent studies suggest <u>one-stage exchange</u> arthroplasty may provide superior outcomes, including lower reinfection rates and superior function, in select patients. Clinically, for some patients, one-stage exchange arthroplasty may represent optimum treatment; <u>however</u>, patient selection criteria and key components of surgical and post-operative anti-microbial management remain to be defined.

ORTHOPAEDIC SURGERY

Reinfection rates after one- and two-stage revision surgery for hip and knee arthroplasty: a systematic review and meta-analysis

Annemarie L. Goud¹ · Netanja I. Harlianto² · Solaiman Ezzafzafi² · Ewout S. Veltman² · Joris E. J. Bekkers¹ · Bart C. H. van der Wal²

Received: 24 April 2021 / Accepted: 24 September 2021 © The Author(s) 2021

Results For hip revision arthroplasty, we identified 14 one-stage studies (n = 1237) with a pooled reinfection rate of 5.7% (95% CI 3.7–8.1%), and 46 two-stage studies (n = 5009) with a reinfection rate of 8.4% (95% CI 6.9–9.9%). For knee revision arthroplasty, <u>6 one-stage studies</u> (n = 527) and <u>48 two-stage studies</u> (n = 4344) were identified with reinfection rates of 12.7% (7.0–19.7%) and 16.2% (13.7–19.0%), respectively. Overall, reinfection rates did not vary substantially after subgroup

Conclusion The reinfection rates following one- and two-stage hip and knee arthroplasty revisions were similar. Knee reinfection rates have increased compared to the previous analysis. Individual patient characteristics and adequate treatment algorithms are needed for a more individual selection approach, until a randomized trial is performed.

■ JOINT ARTHROPLASTY: OPTIMIZING OUTCOMES Indications for a single-stage exchange arthroplasty for chronic prosthetic joint infection

A SYSTEMATIC REVIEW

R. R. Thakrar, S. Horriat, B. Kayani, F. S. Haddad

ed that single-stage exchange arthroplasty be undertaken in the <u>absence of the following features: severe immunosuppression</u> with or without significant systemic disease; concurrent acute <u>local sepsis</u> and soft-tissue or bony compromise not amenable to primary wound closure; and <u>multidrug resistant</u>, <u>polymicro-bial or atypical organisms</u>. The lack of preoperatively identified infective organisms seems to represent a relative contraindication to this procedure.

Authors: Peter Keogh, Andrew Toms, Akos Zahar, Fares Haddad, Shengjie Guo, S. McHale

QUESTION 2: What are the indications and contraindications for a one-stage exchange arthroplasty for the treatment of chronic periprosthetic joint infections (PJIs)?

RECOMMENDATION: One-stage exchange arthroplasty remains a viable option for the management of chronic PJIs. In patients with signs of systemic sepsis, extensive comorbidities, infection with resistant organisms, culture-negative infections and poor soft tissue coverage, one-stage exchange arthroplasty may not be a good option.

LEVEL OF EVIDENCE: Moderate

DELEGATE VOTE: Agree: 93%, Disagree: 5%, Abstain: 2% (Super Majority, Strong Consensus)

Indications for One-stage

Host/Local

- Non-immunocompromised host
- Absence of systemic sepsis
- Minimal bone loss/soft tissue defect allowing primary wound closure
- Microbiology
- Isolation of pathogenic organism preoperatively
- Known sensitivities to bactericidal treatment

Relative Contraindication to One-stage

- Severe damage of soft tissues where the direct closure of the joint and the wound is not possible. A complex sinus tract which cannot be excised along with the old scar.
- Culture-negative PJI, where the causative organism and its susceptibility are not known.
- No radical debridement of infected soft tissues or bone is possible (for whatever reason).
- No local antimicrobial treatment is possible (for whatever reason).
- No proper bone stock exists for the fixation of the new implant.

Conclusions

- 2-stage is the workhorse of PJI treatment
- 1-stage is a viable solution
- Few patients treated in low number of studies
- Strict selection seems varanted (1 in 5 is a candidate?)
- Efficacy compared with 2-stage is unelucidated
