Robotic surgery ?

Navio

Surgical robotics has been shown to improve the accuracy of bone preparation and soft tissue balance in unicompartmental knee arthroplasty (UKA). However, although extensive data have emerged with regard to CT scan-based digitally constrained robotic arm (1), little is known about the accuracy of a more alternative, an imageless robotic system.

The Navio™ Precision Freehand Sculpting system (Navio™, Blue Bird Technologies, Inc., Plymouth, MN, USA) is an imageless handheld robotic arm (Fig. 1). Implant planning and development of the cutting zone take place entirely intraoperatively without the need for a preoperative CT scan. The system continuously tracks the position of the patient's lower limb and the handheld robotic device using an infrared navigation system. The system is incapable in as much as it does not use a CT or MRI to map the femoral and tibial condylar surfaces. It therefore relies on accurate registration of intraoperative knee kinematics, automatic automatic landmarks, and surface mapping of the knee using a calibrated optical probe designed for use with this robotic system.

After percutaneous insertion of bicalcular partially threaded pins into the proximal tibia and distal femur and attachment of optical tracking arrays (Fig. 2), mechanical and

Aims

Ideal component sizing may be difficult to achieve in unicompartmental knee arthroplasty (UKA). Anatomic variants, incremental implant size, and a reduced surgical exposure may lead to over- or under-sizing of the components. The purpose of this was to compare the accuracy of UKA sizing with robotic-assisted techniques versus a conventional surgical technique.
